ADVERTISING AND CONCENTRATION IN THE BREWING INDUSTRY

ABSTRACT

The paper tracks the development in industry concentrations from 2002 to 2012, discusses some of the main drivers behind this development and points to economies of scale in advertising as a main pay-off from mergers and acquisitions. Using firm-level data both from the American market and the world market, the estimations verify significant economies of scale in marketing and distribution costs. Based on information from the annual reports of the eight largest breweries, the estimation proved a reduction in these costs of 10% when doubling the size of the brewing groups.

Key Words: Advertising, mergers and acquisitions, brewing industry

INTRODUCTION

The early 2000s witnessed a radical concentration in the international brewing industry, as noted by researchers and consultancy agents alike (Madsen, Pedersen, and Lund-Thomsen, 2012; Euromonitor, 2010). A significant part of the concentration has been driven by mergers and acquisitions and the impact on market shares has been significant, while so far it seems that positive financial effects are waiting to materialize. While the increasing concentration in the national brewing markets before the turn of the century has been studied in a number of studies for several countries, the globalization of the beer market, where some breweries become global players, has not been dealt with so far.

Increasing economies of scale in plant production has been listed as one of the main factors behind the restructuring of the national brewing industry (see Tremblay, Iwasaki, and Tremblay [2005] and Nelson [2005]). However, plant scale economics cannot be the main driver of the globalization of the industry as the international trade of beer is quite low compared to the home production except for a few small countries. If the large number of cross-border mergers and acquisitions that make the industry more global are motivated in a search for larger profit, one has to look at economies of scale at the multi-plant level where management skills, advertising and transfer of know-how or technology become central factors.

In this study we focus on the role of advertising, which serves to build brand loyalty. In addition, advertising serves to “premium brands” (which may be premium in no other way than being heavily advertised) thus causing an upward pressure on beer prices. From industrial economics it is well known that the structure of advertising costs translates into significant scale advantages. As observed by Tremblay and Tremblay (2005), the industry has travelled through several stages of development each with its own characteristics. Currently the brewing industry has reached a semi-global stage reflecting a mixture of global and multi-domestic features (Porter, 1986).

The main objective of the paper is to analyze the importance of advertising for the trajectory of concentration in the global brewing industry, by looking at the main large brewing groups and their strategies in brand advertising. Section 2 sets the scene by describing the increasing world concentration in the beer industry and by highlighting some of the driving forces put forward in the literature. Section 3 deals with the role of advertising behavior in the brewing industry and explores the economies of scale in marketing activities. Section 4 and 5 present the empirical evidence for economies of scale

in marketing both from the US and the global markets. The results verify significant cost savings by scale in marketing and distributions. Section 6 concludes the paper.

INCREASING WORLD CONCENTRATION IN MASS-PRODUCED BEER

After the Second World War the national beer markets for mass-produced beer went through a dramatic restructuring with increasing concentration everywhere. In the US market the share of the four largest breweries increased from 22 to 95% in the period 1950-2000, reflecting a decrease in the number of independent breweries from above 350 to just 24. The increasing concentration in the market was driven by the growth of a few breweries, where the leading company Anheuser-Busch's market share jumped from 6 to 54% in the period. For a summary of this development in the US market (see Tremblay *et al.* [2005] and Nelson [2005]).

In the last part of the period the so-called microbreweries emerged and they increased dramatically, especially in the first part of the 1990s. This segment of the beer market seems to have matured in the US already at the end of the 1990s when these microbreweries peaked at 1600 in 1998 and stabilized around that number since then. However, the microbreweries or very small specialty brewers often only brew craft-styled beer on a small scale for local consumers, e.g. the customers of a restaurant, therefore their entry into the industry does not change the concentration measures for the whole industry in any significant way.

As observed by Tremblay and Tremblay (2005), the American industry has travelled through several stages of development in this period and each with its own characteristics, but all driven by increasing economies of scale in production. The minimum efficient scale of a production plant increased steadily throughout the period due to new technology with plant automation that increased the speed of canning and bottling lines. Also, the fall in transportation costs increased the economics of plant size as a larger area could be served from a single production plant. As a result Tremblay and Tremblay (2005) calculated that the American beer market could be served by only 15 efficient firms in 1970, when the actual number of firms was 82. The investment in new technology by the large players create an overcapacity or overhang of inefficient breweries in the industry and a brewing war of attrition for profit in that period (see Iwasaki, Seldon and Tremblay [2008]), who provide evidence of significant effects on the breweries' profits.

The fast innovation in communication in this period also contributed to the concentration of the industry as it reduced the market for local beer. This is most forcefully documented by George (2009) who looked at the penetration of television in local markets in the US from 1945 to 1960. She found that the numbers of local breweries were negatively correlated with the fraction of the population with access to a television signal and that the opportunity of national advertising through broadcasting accounted for 27% of the total decline in the market share for the local breweries.

The innovation in production technology and communication in this period forced a concentration in most other national beer markets as well. However, the German markets have lagged behind and Adams (2006) finds that the market structure depends on a broad range of factors, extending well beyond the technological opportunity and market size emphasized by Bain (1966). First, he finds that the consumer preference for locally produced beer is much stronger in Germany and therefore it is more difficult to turn the consumer to nationally promoted brands. Secondly, he finds several politically introduced rules which had delayed the restructuring of the industry. The 'purity' rules, which forbid beers to contain preservatives and thereby increase the cost of transportation, were first challenged by the European Court of Justice in 1987 where Germany had to open the borders to beer produced legally in other European Union countries. Also, television advertising was more costly due to the limited number of commercial channels and limited amount of time for each add which made it much more costly in Germany to reach the drinking males through television.

The increasing concentration in the national beer markets also reduced the number of competitors at a global scale. However, these developments did not change the cross-border competition very much as the international trade in beer and the cross-border ownership holding were low at that time. The turn of the century changed this as the cross-border mergers and acquisitions increased dramatically and made a few of the breweries real world players (see Pedersen *et al.* [2013]).

Figure 1 highlights this increasing global concentration in the brewing industry after the turn of the century where the four firm concentration ratios increased by 113% from a market share of 23 to 49%. While the market share for the four largest firms rose by 113%, it only increased by 54% for the six next largest firms in the industry, so the restructuring of the industry was primarily led by a few large breweries. They became real multinational companies by a strategy of cross-border mergers and acquisitions. The large jump in CR2 of 11% in 2008 is the result of InBevs' acquisition of Anheuser Busch. This

was a mega takeover amounting to €57 billion and it made the new company AB InBev the true leader in the industry with the double size of the next largest company SAB Miller.

Figure 1. Concentration ratios in the global brewing industry

Note: CR2, CR4 and CR10 measure the market share by volume of the two, four and ten largest companies in the worldwide industry. The top down company list of concentration is: AB InBev, SAB Miller, Heineken, Carlsberg, Molson Coors, Kirin, Tsing Tao, Yanjing, Modelo and Asahi.
Source: Market Data Analytics.

Although there has been some increase in the market share of imported beer, it still accounts for less than 10% in most markets. Therefore, beer is mainly produced locally as the transportation cost is quite high due to the heavy weight of these consumer goods. This excludes economies of plant size as a motivating factor for the wave of cross-border mergers and acquisitions after the turn of the century. If there are any synergies of these strategies, they therefore have to be extracted at a higher level in the company from multi-plant operations or economics of scope in handling several brands. At this level sales and marketing management played a central role as it accounts for a large share of the central costs and we will therefore take a closer look at these costs.

THE ROLE OF ADVERTISING

The characteristics of beer have not been clearly defined in the literature. As advertising for individual brands exists, it cannot be a homogenous good and this leads some authors to conclude that beer is a physically heterogeneous product. However, the product quality

or vertical product differentiation does not vary a lot between the brands as the production processes for beer are quite old and have not developed much over the time. The technology is therefore well known and the brewing only includes a few raw materials like water, barley, hops and yeast. Most breweries brew different types of beer, like pilsner or lager, and the production costs do not vary significantly between the different types.

There is some horizontal product differentiation due to different sorts of barley and hops and the mix of the materials in the brewing process. However, within the same categories of beer the difference in tastes is very moderate and the recognition of brands is therefore often not significant in blind tests. While the real product differences are quite small, the differences in product quality revealed by the beer drinkers are on the other hand very large. This is most forcefully illustrated by McConnell (1968), who performed a controlled experiment of the branding effects in the American beer market. In the experiment, 24 home deliveries of six-packs of beer were completed over two months to a large sample of beer drinkers. All the beer was identical, so there were no quality differences at all, but the beer drinkers did not know this as the regular labels were removed and new labels were added with three different prices corresponding to the average price of a popular, premium and super-premium beer at that time. When assessing the quality of the beers the panel ranked the high-priced beer higher in quality with a large margin compared to the low-priced beer. One drinker even said about the brand he thought was cheap, 'I could never finish a bottle'.

As the large breweries produce the different variety of beers and even make some adaptations to the product to fit local taste preferences, it seems that the beer market fulfills the conditions for being a global market, which according to Porter (1986) is a market with a well-defined product, customers with roughly the same needs and the same competitors active in the major markets. However, as there are some small variations in local tastes and long-distance trade and arbitrage are costly, the market has some regional characteristics as well. With a semi-global market for beer and a product with strongly perceived brand preferences of the customers, advertising becomes an important competitive parameter when moving from a national supplier to a global supplier.

The innovation in communication has reduced the costs of advertising due to economies of scale. Especially the emergences of electronic media as radio and television which cover a larger audience and therefore result in lower contact costs than advertising in newspapers. Even if the price per viewer is the same for small and large firms, large firms have advantages as they are present in more markets and therefore do not waste

advertising on viewers who have no option to buy their product. This is the case for local breweries or smaller national brands which are only present in local shops or bars. As the bulk of advertising moved from the newspapers and other printed media to the electronic media which normally cover larger areas, the disadvantages grew for locally based brands.

SOME AMERICAN EVIDENCE

To illustrate the competitive advantages for the large breweries in advertising, we first take a look at the American market. Figure 2 lists the advertising costs in cent per case of 24 beers for the top 3 brewers in the market. The advertising costs are significantly lower for Anheuser Bush which has a market share significantly larger than the combined share of SAB Miller and Coors. This presents some evidence for economies of scale in advertising.

Figure 2. Advertising costs in US\$ per case for the top 3 brewers

Note: A case is 24 cans or 2.25 gallons.
Source: Nelson (2005: 278).

From an economic point of view the advertising cost advantage of the larger breweries can also explain their large market share as the larger price-cost margin gives a higher profit motivation to build new capacity as the return on their investments in capacity is larger. To highlight the size-effect of advertising on the cost efficiency we estimate equation (1) where A is total expenses on advertising and S is the total quantity of beer sold. The estimated parameter α is the size elasticity of advertising and D_j is a dummy for brewery j which has been added to pick up differences in advertising efficiency for the individual brewery.

$$\text{Log (A/S)} = \text{Const} + \alpha \text{Log (S)} + D_i \quad (1)$$

Larger breweries have also a strategic advantage compared to the smaller breweries due to a larger total budget for advertising. The market for advertising is not characterized by perfect competition with a well-defined market price. In some cases only one advertiser is selected and there is a strategic game where ‘the winner takes it all’ and here the deep pocket can make the difference. This is often the situation in advert advertising like sponsorships of sport world championships or the Olympic Games, where deep pockets even is a pre-condition for participation in auctions of the advertising slots. The effect of deep pockets is estimated using equation (2) where the dummy D_i , again has been added to pick up differences in advertising efficiency and the estimated parameter α is the size elasticity of the total advertising budget.

$$\text{Log (A)} = \text{Const} + \alpha \text{Log (S)} + D_i \quad (2)$$

Table 1 lists the estimations results for the top 3 breweries in the US in the 1990 - 2003 period giving a total of 42 observations. The first two models estimate the size effects on the costs of advertising per beer sold. The first model shows that larger breweries have a significantly lower advertising cost per beer sold where a doubling of size reduces the advertising cost with 47%. Introducing dummies for Anheuser Bush and SAB Miller in model (2) turns the sign of the size effects from negative to positive. This reveals that the negative size-effect emerged from cross-firm effects and that the within-firm size effects in this period are positive and significant. This, of course, is a bit strange, but could either be a result of the inflation in advertising costs or a general rise in advertising in the period due to a more tough fight for market shares. The dummies on the other hand clearly show that even after correcting for size the largest brewery Anheuser Bush still has the largest cost advantage in advertising

The last two models estimate the size effect on the total spending on advertising and model (3) clearly verifies a positive effect where a doubling of firm size increases the budget with 57%. This reflects the economies of scale in advertising as the total budget does not increase proportionally and therefore makes rooms for cost efficiencies for the larger brewery. However, the model only explains 7.3% of the variation in the total advertising expenses, and introducing dummies in model (4) increases the R-square

dramatic verifying the high degree of heterogeneity between the breweries. The dummies also increase the within-firm size effects as in model (2) and probably for the same reason. The model shows that correcting for firm size effects Anheuser Bush and SAB Miller have a lower total budget for advertising than Coors, which mirror the cost advantages.

Table 1. Estimation of size effects of advertising and deep pockets in US, 1990 to 2003

It is often claimed that advertising is a useful tool for new firms to enter a mature market as they thereby have an option to inform the customers of their existence and the advantages of their products. However, for some of the big adverts as e.g. sponsorships which cover advertising on a global scale it is very expensive and would only pay off if the brewery has the capacity to serve the whole market. This is, of course, a barrier for a new and small entrant. Further, new firms have to buy their ways into the industry by only one or a few sponsorships. The larger incumbent competitors with the deep pockets then have competitive advantages of several sponsorships and more advertising spots in television which make their brands much more exposed to the consumer and therefore they will earn a higher brand value and the advantages thereof.

SOME WORLD MARKET EVIDENCE

The American evidence of economies of scale in advertising and the globalization in the electronic media raise the question whether these scale advantages in advertising also cross the national borders and could be taped by multinational breweries. If this is the case, the large wave of mergers and acquisitions within the brewing industry during the last fifteen

years could be a response to these cost advantages. To answer this question we analyze the eight largest breweries in the world in 2012. Table 2 shows descriptive statistics for the period 2002 to 2012 on their market share and some cost categories.

Table 2. Period average of selected items for the 8 largest breweries in the world, 2002–2012

Company	World market share	Marketing costs (Share in revenue)	Distribution costs (Share in revenue)	Production costs (Share in revenue)
AB InBev	0.14	0.16	0.10	0.44
SAB Miller	0.12	-	0.12	-
Heineken	0.07	0.13	0.06	-
Carlsberg	0.04	0.19	0.13	0.50
Molson Coors	0.04	0.29	-	0.60
Kirin	0.03	0.15	0.04	0.51
Tsing Tao	0.03	0.17	0.04	0.61
Yanjing	0.02	0.10	0.02	0.61

Note: Share of marketing, distribution and production costs relative to net revenues. All shares are calculated as an average over the period. Data from Kirin begins in 2006 and there is no information for marketing in the annual report from SAB Miller.

Source: Cost share from companies' annual reports and world market share from Market Data Analytics Database.

The costs are reported as share of net revenue and the costs of marketing also include sales expenses as the different types of sales and marketing costs are aggregated in their annual report. However, a high portion of the sales expenses in the beer industry have the character of advertising as it includes expenses for sales agents and equipment for shops and bars such as desks and refrigerators. Distribution costs are distribution expenses and production costs are costs of goods sold. The breweries use the same terms for the cost categories in their annual reports, but the methods of calculation could vary between the breweries. To take care of this heterogeneity in cost accounting, the estimation below used a method with fixed effects for companies as well.

The large breweries have many different brands and advertising campaigns are often targeted to a specific brand. Wilcox (2001) studied beer brand advertising and their market share in the US from 1977 to 1998. Of the 11 brands studied he only found a significant relation between advertising and market share for 8 brands. However, even if the costs of advertising could be split up on the different brands, the individual brand effects may correlate within the brands of the brewery and then the other brands of the same company, e.g. an advertising campaign for Bud Light may also affect the sales of

Budweiser. Therefore, the total costs of sales and marketing activities for the brewery is a more precise measure to validate the amount and effects of these activities.

In the period from 2002 to 2012 the concentration more than doubled from 22% to 50% in the global market for mass-produced beer, as listed above, and this restructuring of the industry was mainly driven by high growth among the top 4 breweries which more than doubled their size. To see how this growth in size affects the costs of marketing, Figure 3 pictures the development in the share of marketing and sales costs. Of the seven breweries that publish their sales and marketing costs five experienced a fall in this cost share which gives some evidence for the economies of scale in marketing as most of the large brewery groups costs decline. To study the size effects further equation (3) has been estimated where (C_k/R) is the cost share in net revenue for marketing and distribution costs. The estimated parameter α is the size elasticity of the two cost types with respect to the world market share, WS, and β_i is a fixed effect for company i pick up differences in costs efficiency and accounting practices for the individual brewery.

$$(C_k/R) = \text{Const} + \alpha \text{WS} + \beta_i \quad (3)$$

Table 3 presents the results of the estimations of these size effects for both marketing costs and distribution costs using the breweries' world market share as a measure of size. The simple OLS regressions do not show any significant negative size effect but a significant positive size effect in the distribution costs. This may be interpreted as if the small breweries, on average, are as cost-efficient as the large ones. This is especially true for the distribution costs where the size relationship is significant positive. However, using fixed effects for the breweries the coefficient turns significant negative for both marketing and distribution shares. Thus, the within-company size effect is negative, showing that the breweries earn large cost efficiencies when they increase their market share. The size effect is larger in marketing and sales where an increase in the world market share of 1% will reduce the cost share with 0.298% point whereas the cost share for distribution reduces by 0.202%.

The fixed effect or the heterogeneity between the breweries which makes the smaller breweries more cost-efficient could be the result of different accounting principles as mentioned above. This could be the case for the share of distribution costs which are remarkably low in East Asia. It could also be based on regional differences where branded

premium beer has a larger share of the consumption in the developed countries with more sales and marketing costs.

Figure 3. Development in the share of marketing and sales costs for 7 large breweries

Note: Share of marketing and sales costs in net turnover. Kirin first from 2006 and no information in the annual report from SAB Miller
 Source: Cost share from companies' Annual Reports.

Table 3. Estimation of size effects in marketing and distribution costs

Dependent variable	Marketing cost share	Distribution cost share	Marketing cost share	Distribution cost share
	Simple OLS		Fixed effects	
Intercept	0.176** (0.011)	0.060** (0.009)		
World market share	-0.151 (0.156)	0.285** (0.097)	-0.298** (0.072)	-0.204** (0.050)
R-square	0.013	0.129	0.945	0.948
Observations	73	60	73	60

Note: * p<0.01, * p<0.05.

Source: Cost share from companies' annual reports and world market share from Market Data Analytic.

The size effects could also be estimated directly by regressing the cost components on net revenue and equation (4) shows the estimated model with a log transformation of the variable. C_k is the cost components, R the net revenue, the estimated parameter α is the scale elasticity of the cost component with respect to net revenue and β_i is a fixed effect for company i that pick up differences in costs efficiency and accounting practices for the individual brewery.

$$\text{Log}(C_k) = \text{Const} + \alpha \text{Log}(R) + \beta_j \quad (4)$$

Table 4 presents the results of the estimations and the size effect is highly significant in this formulation as the variables are integrated due to the inflation and the general growth of the breweries. What is of importance, however, is the size of the coefficient, particularly if it is below 1. If so, costs rise less than proportional with sales.

Table 4. Estimation of size effects in production, marketing and distribution costs

Dependent variables (log)	Production costs	Distribution costs	Marketing costs	Production costs	Distribution costs	Marketing costs
	Simple OLS			Fixed effects		
Intercept	-0297 (0.088)	-2.119 (0.549)	-1.557 (0.241)			
Net revenue (log)	0.969** (0.009)	0.947 (0.052)	0.971 (0.024)	0.990 (0.016)	0.881** (0.047)	0.902** (0.030)
R-square	0.995	0.850	0.958	0.999	0.995	0.997
Observations	62	60	73	62	60	73

Note: * p<0.01, * p<0.05.

Source: Net sales and costs from the companies' annual reports.

All models have estimated coefficients lower than 1. In the simple OLS regressions the coefficient is not statistically significant, except for the sales costs. But after correcting for firm heterogeneity in the fixed effect models, the within-firm size effect is significant below one for both marketing and distribution costs whereas the production costs are insignificant different from one and the production costs therefore rise proportional with the increase in net revenue. This verifies that the economies of scale in production have been exhausted. So, further economies of scale in this period emerged from multi-plant operations. The economies of scale in marketing and distribution are quite large as these costs only increase by about 90% when net revenue doubles, creating a cost saving of about 10%. As the marketing and sales costs have high cost shares they also return a large gain in cost savings by company growth.

The large economies of scale in marketing and distribution for the large multinational breweries in the periods after the turn of the century could explain the large wave in

mergers and acquisitions in the same period. Furthermore, the investments in branding also represent a sunk cost that creates an entry barrier as discussed above, and this creates first-mover advantages in the world market for beers. This opened a competitive race between the large breweries during the 1990s after the rather abrupt opening up of the global market with an increasing concentration and a few large dominating breweries left on the playing fields.

These first-mover advantages have not materialized in a superior return for the largest breweries compared with the 100 next largest breweries (see Madsen *et al.* [2012]). The reason for this is still unclear, and there are several possible explanations. First, the market power hypothesis, which states that the rise in market concentration increases the market price and the profits for all the breweries in the industry. Next, in the restructuring process of the industry the acquiring companies have to pay a premium for the acquired breweries. So, most of the synergies from the scale benefit go to the owner of the acquired brewery and leave the acquirer with a larger capital cost. Finally, it may take some time to realize all the synergies from the investment in growth through a merger and acquisition strategy so it has not yet shown up on the bottom line.

CONCLUSION

The opening of the markets in East Asia and Eastern Europe in the 1990s changed the structure of the beer markets and in the following years a large wave of mergers and acquisitions took place. The paper tracks the development in industry concentrations from 2002 to 2012, discusses some of the main drivers behind this development and points to economies of scale in advertising as a main pay-off from mergers and acquisitions.

Using firm-level data both from the American market and the world market, the estimations verify significant economies of scale in marketing and distribution costs. Based on information from the Annual Reports of the eight largest breweries, the estimation proved a reduction in these costs of 10% when doubling the size of the brewing groups.

These scale advantages in the brewery industry created a playing field on the world market for the breweries after the opening of the new markets in the East where the first movers earn competitive advantages. As the entry barriers for mass-produced beers are high in the world market and the treads from new innovation are low due to the nature of

the product these new dominating brewing groups probably can look forward to a long life.
